SNN: TODO and test (12th Oct -)

Omar Abbas Haque

October 2026

1 What tests are worth doing

1.1 Why 9 is biased post-accuracy spike

Theoretically, if we removed the bias towards 9, we get a near-100 percent accuracy network. Try normalizing the inputs

1.2 Network designs without an accuracy spike

Might be worth running the previous test suite over a network design with no accuracy spike

1.3 Less inhibition

"200.0 mV inhibition causes one neuron to win the entire window". Does it really?
Then try architectures with less inhibition (or tell Sunny to do that)

2 Observations

2.1 50 neurons are doing all the work:

Looking at F2 for theta_plus=1 tests, accuracy spike happens at 350 untrained neurons. Actually maybe not, because the highest percentage of spikes come from untrained neurons
